Chapter 4: Network Layer

Chapter goals:

- r understand principles behind network layer services:
 - m routing (path selection)
 - m dealing with scale
 - m how a router works
 - m advanced topics: IPv6, multicast
- r instantiation and implementation in the Internet

Chapter Overview:

- r network layer services
- r routing principle: path selection
- r hierarchical routing
- r IP
- r Internet routing protocols reliable transfer
 - m intra-domain
 - m inter-domain
- r what's inside a router?
- r IPv6
- r multicast routing

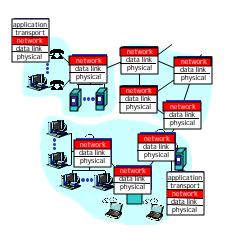

4: Network Layer 4a-1

Network layer functions

- r transport packet from sending to receiving hosts
- r network layer protocols in every host, router

three important functions:

- r path determination: route taken by packets from source to dest. Routing algorithms
- r *switching:* move packets from router's input to appropriate router output
- r call setup: some network architectures require router call setup along path before data flows

Network service model

Q: What service model for "channel" transporting packets from sender to receiver?

- r guaranteed bandwidth?
- r preservation of inter-packet timing (no jitter)?
- or loss-free delivery?
- r in-order delivery?
- congestion feedback to sender?

The most important abstraction provided by network layer:

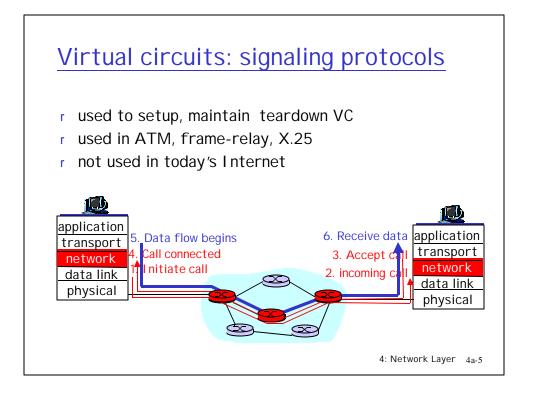

virtual circuit or datagram?

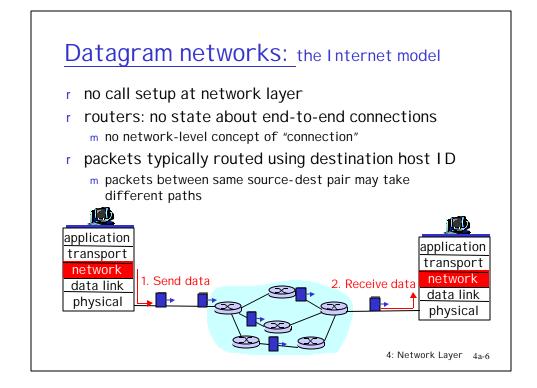

4: Network Layer 4a-3

Virtual circuits

"source-to-dest path behaves much like telephone circuit"

- m performance-wise
- m network actions along source-to-dest path
- r call setup, teardown for each call before data can flow
- r each packet carries VC identifier (not destination host OD)
- r every router on source-dest path s maintain "state" for each passing connection
 - m transport-layer connection only involved two end systems
- r link, router resources (bandwidth, buffers) may be allocated to VC
 - m to get circuit-like perf.

Network layer service models:

	Network	Service	Guarantees ?				Congestion
Architecture		Model	Bandwidth	Loss	Order	Timing	feedback
_	Internet	best effort	none	no	no	no	no (inferred via loss)
	ATM	CBR	constant rate	yes	yes	yes	no congestion
	ATM	VBR	guaranteed rate	yes	yes	yes	no congestion
•	ATM	ABR	guaranteed minimum	no	yes	no	yes
	ATM	UBR	none	no	yes	no	no

- r Internet model being extented: Intserv, Diffserv
 - m Chapter 6

4: Network Layer 4a-7

Datagram or VC network: why?

Internet

- r data exchange among computers
 - m "elastic" service, no strict timing req.
- r "smart" end systems
 (computers)
 - m can adapt, perform control, error recovery
 - m simple inside network, complexity at "edge"
- r many link types
 - m different characteristics
 - m uniform service difficult

ATM

- r evolved from telephony
- r human conversation:
 - m strict timing, reliability requirements
 - m need for guaranteed service
- r "dumb" end systems
 - m telephones
 - m complexity inside
 network

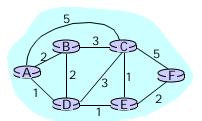

Routing

-Routing protocol-

Goal: determine "good" path (sequence of routers) thru network from source to dest.

Graph abstraction for routing algorithms:

- r graph nodes are routers
- r graph edges are physical links
 - m link cost: delay, \$ cost,
 or congestion level

- r "good" path:
 - m typically means minimum cost path
 - m other def's possible

4: Network Layer 4a-9

Routing Algorithm classification

Global or decentralized information?

Global:

- r all routers have complete topology, link cost info
- r "link state" algorithms

Decentralized:

- r router knows physicallyconnected neighbors, link costs to neighbors
- r iterative process of computation, exchange of info with neighbors
- r "distance vector" algorithms

Static or dynamic?

Static:

r routes change slowly over time

Dynamic:

- r routes change more quickly
 - m periodic update
 - m in response to link cost changes

A Link-State Routing Algorithm

Dijkstra's algorithm

- r net topology, link costs known to all nodes
 - m accomplished via "link state broadcast"
 - m all nodes have same info
- r computes least cost paths from one node ('source") to all other nodes
 - m gives routing table for that node
- r iterative: after k iterations, know least cost path to k dest.'s

Notation:

- r C(i,j): link cost from node i
 to j. cost infinite if not
 direct neighbors
- r D(v): current value of cost of path from source to dest. V
- r p(v): predecessor node
 along path from source to
 v, that is next v
- r N: set of nodes whose least cost path definitively known

4: Network Layer 4a-11

4: Network Layer 4a-12

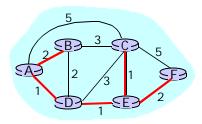

Dijsktra's Algorithm

```
1 Initialization:
2 N = \{A\}
3 for all nodes v
     if v adjacent to A
5
      then D(v) = c(A,v)
6
      else D(v) = infty
8 Loop
    find w not in N such that D(w) is a minimum
10 add w to N
11
     update D(v) for all v adjacent to w and not in N:
       D(v) = \min(D(v), D(w) + c(w,v))
13 /* new cost to v is either old cost to v or known
     shortest path cost to w plus cost from w to v */
15 until all nodes in N
```

Dijkstra's algorithm: example

Step	start N	D(B),p(B)	D(C),p(C)	D(D),p(D)	D(E),p(E)	D(F),p(F)
→ 0	Α	2,A	5,A	1,A	infinity	infinity
1	AD	2,A	4,D		2,D	infinity
	ADE	2,A	3,E			4,E
→ 3	ADEB		3,E			4,E
4	ADEBC					4,E
	∧DEDCE					

4: Network Layer 4a-13

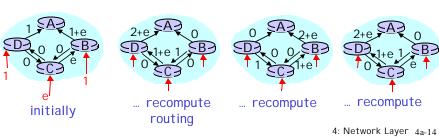

Dijkstra's algorithm, discussion

Algorithm complexity: n nodes

- r each iteration: need to check all nodes, w, not in N
- r n*(n+1)/2 comparisons: O(n**2)
- r more efficient implementations possible: O(nlogn)

Oscillations possible:

r e.g., link cost = amount of carried traffic

Distance Vector Routing Algorithm

iterative:

- r continues until no nodes exchange info.
- r self-terminating: no "signal" to stop

asynchronous:

r nodes need not exchange info/iterate in lock step!

distributed:

r each node communicates *only* with directly-attached neighbors

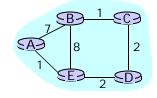

Distance Table data structure

- r each node has its own
- r row for each possible destination
- r column for each directlyattached neighbor to node
- r example: in node X, for dest. Y via neighbor Z:

$$\begin{array}{c} X \\ D (Y,Z) \end{array} = \begin{array}{c} \text{distance } from \ X \ to \\ Y, \ via \ Z \ as \ next \ hop \\ = \ c(X,Z) + \min_{W} \{D^{Z}(Y,w)\} \end{array}$$

4: Network Layer 4a-15

Distance Table: example

$$D^{E}(C,D) = c(E,D) + \min_{W} \{D^{D}(C,w)\}$$

$$= 2+2 = 4$$

$$D^{E}(A,D) = c(E,D) + \min_{W} \{D^{D}(A,w)\}$$

$$= 2+3 = 5 \text{ loop!}$$

$$D^{E}(A,B) = c(E,B) + \min_{W} \{D^{B}(A,w)\}$$

$$= 8+6 = 14 \text{ loop!}$$

cost to destination via

Distance table gives routing table

D	E()	st to d	estinat B	tion via D			Outgoing link to use, cost
	Α	1	14	5		Α	A,1
noitanitael	В	7	8	5		В	D,5
	С	6	9	4		С	D,4
	D	4	11	2	roitanitae	D	D,4

Distance table — Routing table

4: Network Layer 4a-17

Distance Vector Routing: overview

I terative, asynchronous:

each local iteration caused by:

- r local link cost change
- r message from neighbor: its least cost path change from neighbor

Distributed:

- r each node notifies neighbors only when its least cost path to any destination changes
 - m neighbors then notify their neighbors if necessary

Each node:

wait for (change in local link cost of msg from neighbor)

recompute distance table

if least cost path to any dest has changed, notify neighbors

Distance Vector Algorithm:

At all nodes, X:

```
1 Initialization:
2 for all adjacent nodes v:
3 D (*,v) = infty /* the * operator means "for all rows" */
4 D (v,v) = c(X,v)
5 for all destinations, y
6 send min D (y,w) to each neighbor /* w over all X's neighbors */
```

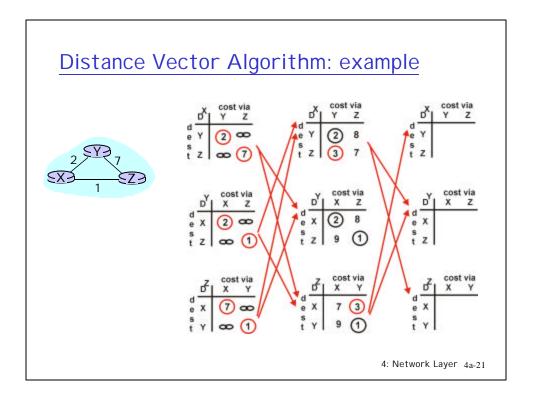

4: Network Layer 4a-19

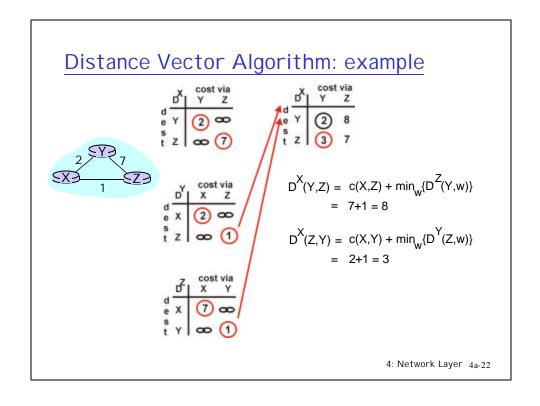

Distance Vector Algorithm (cont.):

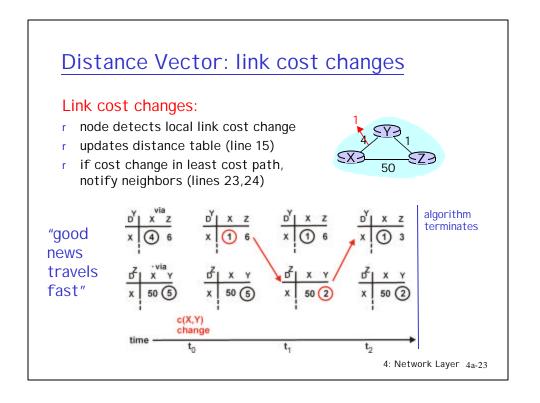

```
→8 loop
 9 wait (until I see a link cost change to neighbor V
          or until I receive update from neighbor V)
 10
 12 if (c(X,V)) changes by d)
 13 /* change cost to all dest's via neighbor v by d */
 14 /* note: d could be positive or negative */
 15 for all destinations y: D^{X}(y,V) = D^{X}(y,V) + d
 16
 17 else if (update received from V wrt destination Y)
 18 /* shortest path from V to some Y has changed */
 19 /* V has sent a new value for its min DV(Y,w) */
     /* call this received new value is "newval"
 20
       for the single destination y: D^{X}(Y,V) = c(X,V) + newval
 21

    if we have a new min<sub>w</sub> D<sup>X</sup>(Y,w)for any destination Y
    send new value of min<sub>w</sub> D<sup>X</sup>(Y,w) to all neighbors

 25
 26 forever
                                                            4: Network Layer 4a-20
```

Distance Vector: poisoned reverse If Z routes through Y to get to X: r Z tells Y its (Z's) distance to X is infinite (so Y won't route to X via Z) r will this completely solve count to infinity problem? DY X Z D X Z D X Z D X Z D X Z D X Z D X Z D X Z S D X

Comparison of LS and DV algorithms

Message complexity

- r <u>LS:</u> with n nodes, E links, O(nE) msgs sent each
- r <u>DV:</u> exchange between neighbors only
 - m convergence time varies

Speed of Convergence

- r <u>LS:</u> O(n**2) algorithm requires O(nE) msgs
 - m may have oscillations
- r DV: convergence time varies
 - m may be routing loops
 - m count-to-infinity problem

Robustness: what happens if router malfunctions?

LS:

- m node can advertise
 incorrect link cost
- m each node computes only its *own* table

DV:

- m DV node can advertise incorrect path cost
- m each node's table used by others
 - error propagate thru network

Hierarchical Routing

Our routing study thus far - idealization

- r all routers identical
- r network "flat"
- ... not true in practice

scale: with 50 million destinations:

- r can't store all dest's in routing tables!
- r routing table exchange would swamp links!

administrative autonomy

- r internet = network of
 networks
- r each network admin may want to control routing in its own network

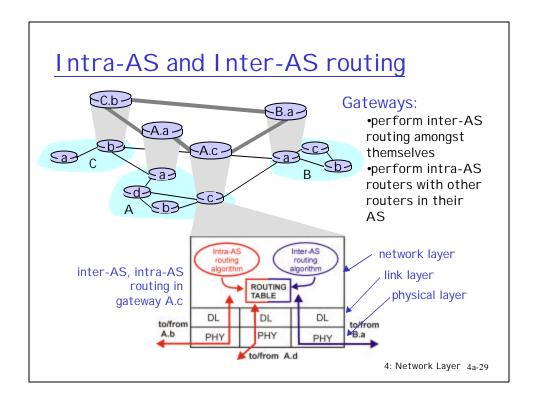

4: Network Layer 4a-27

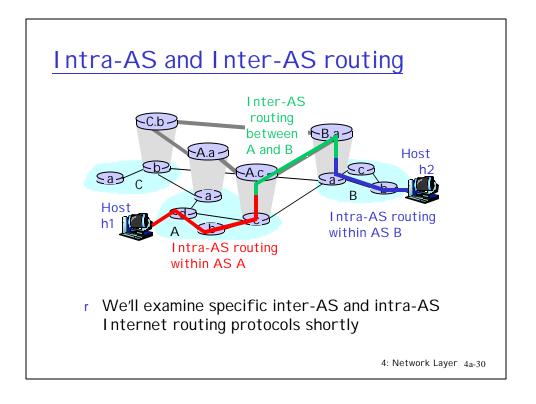

Hierarchical Routing

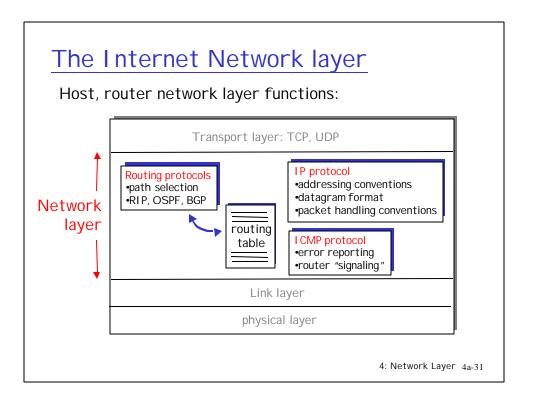

- r aggregate routers into regions, "autonomous systems" (AS)
- r routers in same AS run same routing protocol
 - m "inter-AS" routing
 protocol
 - m routers in different AS can run different inter-AS routing protocol

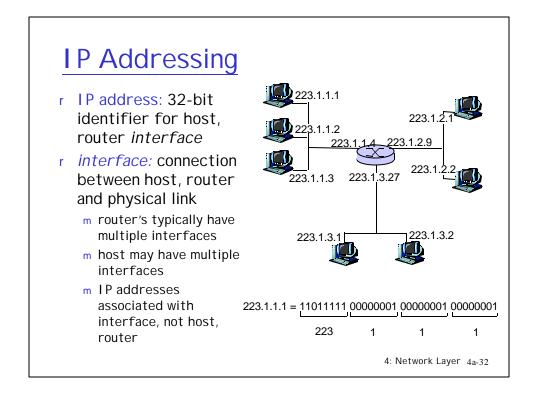

gateway routers

- r special routers in AS
- r run inter-AS routing protocol with all other routers in AS
- r also responsible for routing to destinations outside AS
 - m run *intra-AS routing* protocol with other gateway routers

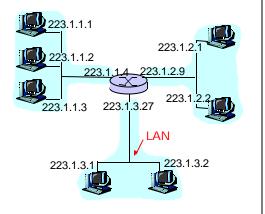

IP Addressing

- r IP address:
 - m network part (high order bits)
 - m host part (low order bits)
- r What's a network?

(from IP address perspective)

- m device interfaces with same network part of IP address
- m can physically reach each other without intervening router

network consisting of 3 IP networks (for IP addresses starting with 223, first 24 bits are network address)
